trophon[®] Efficacy Against Monkeypox Virus

Multiple cases of monkeypox have been reported in several non-endemic countries. Monkeypox is a viral disease with symptoms similar to those seen in smallpox patients. although clinically less severe. Transmission can result from close contact with respiratory secretions, skin lesions of an infected person or recently contaminated objects.

Studies are currently underway to further understand the epidemiology, sources of infection, and transmission patterns of the most recent outbreak.¹

Susceptibility to disinfectants

Monkeypox virus (MPXV) is a double-stranded DNA virus, a member of the Orthopoxvirus genus within the *Poxviridae* family.¹ Orthopoxviruses are enveloped viruses and are therefore within the group of pathogens most sensitive to inactivation by disinfectants.² Orthopoxviruses may be less sensitive to organic disinfectants than other enveloped viruses due to their reduced envelope lipid content.³

Vegetative bacteria, fungi, non-enveloped viruses and bacterial spores all show sequentially increasing resistance to disinfectants and are harder to inactivate than the enveloped viruses.²

trophon disinfectant efficacy

The trophon family includes the CE marked trophon EPR and trophon2 high level disinfection devices, which share the same core technology of sonically-activated hydrogen peroxide.

trophon has been tested according to EN standards and has been demonstrated to be virucidal, bactericidal, fungicidal and mycobactericidal.⁴⁻⁷

While trophon has not been directly tested against monkeypox virus, this pathogen falls into the category of enveloped viruses, the most susceptible category of pathogens to disinfectants. trophon has been demonstrated to be effective against enveloped and nonenveloped viruses as well as other organism groups showing higher resistance to disinfectants than enveloped viruses (Figure 1).
